Validation of the long- and short-form of the Ethical Values Assessment (EVA): A questionnaire measuring the three ethics approach to moral psychology

Laura Maria Padilla-Walker1 and Lene Arnett Jensen2

Abstract

Moral psychology has been moving toward consideration of multiple kinds of moral concepts and values, such as the Ethics of Autonomy, Community, and Divinity. While these three ethics have commonly been measured qualitatively, the current study sought to validate the long and short forms of the Ethical Values Assessment (EVA), which is a questionnaire developed on the basis of the standard coding manual for the three ethics. Two studies were conducted, the first with a sample of 551 college students (18–29 years, 60% female, 61% European American) and the second with a nationally representative sample of 1,519 individuals (18–93 years, 51% female, 72% European American). Results from Study 1 indicated that a three factor solution using the EVA_L (long form) had adequate model fit, and internal reliability and validity of all three subscales were established. Results from Study 2 showed that model fit for a three-factor solution using the EVA_S (short form) was also acceptable. Measurement invariance as a function of age was established for some subscales and age groups, but not others. Discussion focuses on the implications of this measure for moral psychology and important future research directions.

Keywords

autonomy, community, divinity, early adulthood, emerging adulthood, EVA, later adulthood, middle adulthood, moral reasoning, three ethics

In recent decades, an argument for multiplicity has gained traction in the study of human psychology. Instead of a focus on one kind of self, one kind of intelligence, and one kind of creativity, for example, researchers have described multiple selves (Markus & Kitayama, 1991; Miller, Das, & Chakravarthy, 2011; Triandis, 1995), intelligences (Gardner, 1993; Sternberg, 1985, 2004), and creativities (Csikszentmihalyi, 1988; Kaufman & Bhegetto, 2009; Lubart, 1999). Moral psychology, too, has seen calls for the inclusion of multiple kinds of moral concepts and values (Colby & Damon, 1992; Dief, 1982; Gilligan, 1982; Miller, 1989; Padilla-Walker & Carlo, 2014; Shweder, 1990; Trommsdorff, 2012). More often than not, the arguments for multiplicity have been inspired by consideration of culturally diverse individuals and groups.

One approach to capturing diversity in peoples’ moral psychology differentiates between the three Ethics of Autonomy, Community, and Divinity (Jensen, 1995, 2015; Shweder, 1990; Shweder, Much, Mahapatra, & Park, 1997). Briefly, the Ethic of Autonomy involves a focus on persons as individuals. Moral considerations within this ethic address the interests, well-being, and rights of individuals (self or other), and fairness between individuals. The Ethic of Community focuses on persons as members of social groups, such as family and society. Here moral considerations include duty to others, and concern with the welfare, interests, and customs of groups. The Ethic of Divinity focuses on persons as spiritual or religious beings, and moral considerations encompass divine and natural law, sacred lessons, and spiritual purity.

The majority of research with the three ethics has involved interviews. There is by now a substantive body of findings showing the use of these ethics across diverse cultural and age groups. In order to broaden research on the ethics and to relate their use to other measures, however, the availability of a questionnaire for assessing use of the three ethics would be beneficial. The present aim was to validate the Ethical Values Assessment (EVA), a questionnaire that was recently developed for measuring the three ethics and that consists of both a long (EVA_L) and short (EVA_S) form. In the following, a review of previous research on the three ethics is followed by a description of the development of EVA.

Previous research on the ethics of autonomy, community, and divinity

Research with the three ethics has primarily involved the coding of oral discourse, such as from interviews with individual research participants (e.g., Arnett, Ramos, & Jensen, 2001; Hickman, 2014; Kapadia & Bhangaokar, 2015) or conversations between participants (DiBianca Fasoli, 2013; Hickman & DiBianca Fasoli, 2015). These materials have been analysed with the standard coding

characterized by a quest for self-determination and exploration that afford a period of emerging adulthood—a developmental time among people in their late teens and twenties who live in cultures objective (Hickman & DiBianca Fasoli, 2015; Jensen, 2015). The kar, 2015), and among religiously conservative American commu-
tically are placed ahead of the individual (Kapadia & Bhangao-
children and adolescents in India where family and community 
Ethic of Autonomy has been found to be lower among adults than 
modulates with culture (Jensen, 2008, 2015). For example, the 
Ecology of Autonomy, Community and 
EVA: A new measurement of the three ethics

A questionnaire, the Ethical Values Assessment (EVA), was cre-
ated in order to facilitate such additional research with the three 
ethics. Compared to the coding of discourse, a questionnaire gen-
erally allows for data collection that is more time efficient and 
includes larger samples. It can also easily be distributed together 
with measures of other variables.

An 18-item EVA long form (EVA_L) was developed first, with 
a 12-item short form (EVA_S) being based off of the long form (as 

described in what follows). Having both long and short forms 
allows researchers a choice based on their study aims and logis-
tics. For example, the distribution of a large battery of question-

naires to a nationally-representative sample (as in the present 
Study 2) places a premium on space, making EVA_S the best, 
or even only, choice. In contrast, for new research with culturally 
diverse groups, EVA_L (with its 50% additional items) is likely to 
be the better option. Interview research on the three ethics has 
shown that cultures vary on the salience of subcategories within 
each ethic (Jensen, 2015). In fact, this is why the standard 
coding manual comprises quite a large number of subcategories. 
The individual items on EVA constitute the equivalent of such 
subcategories (as described in more detail in what follows). Thus 
for new research in different cultures, having 18 rather than 12 
items enhances the likelihood of the inclusion of numerous cultu-
rally salient items, and diminishes the risk of ending up with an 
insufficient number of such items.

Items for EVA_L were developed on the basis of the standard 
coding manual for the three ethics (Jensen, 2015). Table 1 lays 
out how the individual EVA items map onto subcategories from 
the standard coding manual. The following criteria guided the 
ineclusion of items: 1) Items were based on the subcategories used 
most often by adolescents and adults across diverse cultures 
(Jensen, 2015). The coding manual includes a total of 42 
subcategories, but a number of these occur infrequently (e.g., 
means-ends considerations) or are more typical of children 
(e.g., avoiding punishment to self). EVA_L only comprises items 
that correspond to common subcategories. 2) Items were 

included in order to represent important different facets within 
each ethic. For example, items for the Ethic of Autonomy per-
tained both to the self and other individuals. For the Ethic of 
Community, items encompassed different groups such as family 
and society. For the Ethic of Divinity, items pertained to God and 
individual spirituality. 3) Total number of items was kept to a 
number that would allow for the use of the EVA_L in a wide 
variety of studies.

As described, the questionnaire items represent moral concepts 
that previous research has shown to be quite common across numer-
cous cultural groups. In order to further enhance the cross-cultural 
applicability of the questionnaire, it also includes an open-ended 
question that allows participants to indicate three additional ethical 
values of importance to them. On the EVA, participants are asked to 
respond to the following probe: “What moral values do you think 
are important to how you should live your life at this time in your 
life?” (Arnett et al., 2001). A probe pertaining to people’s own lives 
(as opposed to a hypothetical person or other people in general) was 
used because research findings on moral reasoning and moral

manual for the three ethics (Jensen, 2015). The standard coding pro-
cedure calls for each of a participant’s moral reasons to be coded 
into one of the ethics. Each reason is also coded into one of numer-
ous subcategories. The manual differentiates 13 to 16 subcategories 
for each ethic, such as “Self’s Psychological Well-Being” and 
“Rights” for Autonomy, “Duty to Others” and “Social Order or 
Harmony Goals” for Community, and “Scriptural Authority” and 
“God-Given Conscience” for Divinity. Coding for both ethic and 
subcategory facilitates comprehensive and detailed coding of a per-
son’s moral reasons. The standard coding manual was originally 
developed on the basis of a wide-ranging review of developmental 
and cultural research in order to cull a full scope of moral concepts.

Findings have shown the presence and reliable differentiation 
of the three ethics among notably diverse cultural groups, includ-
ing groups from Brazil, Finland, India, the Philippines, and the 
US (e.g., Guerra, Giner-Sorolla, & Vasiljevic, 2013; Jensen, 
1997, 1998; Rozin, Lowery, Imada, & Haïdt, 1999; Vainio, 
2015; Vasquez, Keltner, Ebenbach, & Banaszynski, 2001). Recent 

studies have also largely supported the cultural-developmental 
proposal that life course development of the three ethics co-
modules with culture (Jensen, 2008, 2015). For example, the 
Ethic of Autonomy has been found to be lower among adults than 
children and adolescents in India where family and community 
typically are placed ahead of the individual (Kapadia & Bhangao-
kar, 2015), and among religiously conservative American commu-

nities where submission of the self to divinity is a paramount 
objective (Hickman & DiBianca Fasoli, 2015; Jensen, 2015). The 
Ethic of Autonomy has also been shown to be particularly popular 
among people in their late teens and twenties who live in cultures 
that afford a period of emerging adulthood—a developmental time 
characterized by a quest for self-determination and exploration 
(Arnett, 2004). In one study, emerging adults in Brazil, Israel, New Zealand, and the UK placed Autonomy above the other two 
ethics. The interesting, if not entirely surprising, exception was Japan where Autonomy was tied with Community (Guerra & 
Giner-Sorolla, 2015). Another study of Hmong dyads in the US 
found that emerging adults gave preference to the Ethic of Auton-
omy whereas their parents did not (Hickman, 2014).

The intersection of culture and development has also been 
observed for the other two ethics. Studies in India, for example, 
have shown that the Ethic of Community is higher among adults 
than adolescents (Kapadia & Bhangao- 
kar, 2015), and that the Ethic of Divinity emerges early in both low- and high-SES children (Pandya & Bhangao-
kar, 2015). These two results, respecti-
vely, are likely shaped by the Indian family and group-
orientation noted above, and the suffusion of religion in everyday 
life in India. The Ethic of Divinity has also been found to remain 
high among religiously conservative emerging adults from the US, reflecting how religious culture shapes development (Padilla-

In sum, research with the Ethics of Autonomy, Community and 
Divinity has proven fruitful in describing multiplicity in peoples’ 
moral psychology, and how trajectories of development for each 

ethic co-modulate with culture. Additional research is needed, 
however, to further examine the intersection of culture and de-
velopment in use of the three ethics (Jensen, 2015), including how 
this intersection is related to context (Miller, 2015). Cultural-
developmental research examining how the ethics are connected 
to other cognitive, emotional, and behavioral variables is also 
needed (Trommsdorff, 2015a). Finally, the measurement of the 
three ethics in conjunction with other approaches to morality from 
evolutionary and social psychology as well as neuroscience would 
also add valuable new knowledge (Sunar, 2009).
identity show that people invoke more diverse moral concepts when asked about their own lives, including personal goals and spiritual-ity (e.g., Colby & Damon, 1992; Damon & Colby, 2015; Walker, 2013; Walker, Pitts, Hennig, & Matsuba, 1995). Furthermore, for purposes of assessing how people’s use of the three ethics are connected to other cognitive, emotional, and behavioral variables in their lives, it seemed important to ask about their own values. For example, asking about the moral values that a person considers important for herself is more likely to be relevant to her moral behav-

ors than asking about others (Blasi, 1984, 1993; Hardy, Walker, Olsen, Woodbury, & Hickman, 2013). Depending on the aims of researchers, however, the probe for EVA may be substituted or supple-

mented. For example, an option would be to ask: “What moral values do you want to pass on to the next generation?” (Arnett et al., 2001). Additionally, researchers have the option of asking participants to indicate their top three moral values. The final fine-tuning of the phrasing of the EVA_L items, probe, and answer options involved reviews by moral psychology researchers and focus groups of lay people.

Thus, the present aim was to assess the validity of the EVA (long and short forms) among English speaking individuals from the United States. Two studies were carried out with different samples in order to examine the measure among individuals of diverse ages. The sample for the first study was comprised of college students, while the second study included adults ages 18–90+. Our specific goals were to validate both EVA_L and EVA_S using Confirmatory Factor Analysis (CFA) (Studies 1 and 2), examine cross-sectional correlates of each ethic (Study 1), and examine differences in the three ethics as a function of age (Study 2).

Study 1
As noted above, it is quite common for emerging adults to highly endorse an Ethic of Autonomy, although they have also been found to balance Autonomy and Community ethics in some con-
texts and cultures (Guerra & Giner-Sorolla, 2015). While the Ethic of Divinity is thought to be endorsed rarely by this age group, it may be prominent for emerging adults who are religious

Informed consent was obtained online, and only after consent was accessed the study website with a class-specific recruitment code. Interested students then combined income of over US$100,000. Adults were European American (61\%), Latino American, 5\% female). Participants were recruited from four universities across the United States, with an overall response rate of approximately 60\%. The majority of emerging adults were European American (61\% European American, 25\% Asian American, 5\% Latino American, 5\% mixed-biracial, and 4\% African American). Nearly 90\% of emerging adults reported living outside of their parents’ home in an apartment, house, or dormitory. Roughly 20\% of emerging adults had parents with a combined income of less than US$50,000 per year, and about 30\% with a combined income of over US$100,000.

Participants were recruited through faculty’s announcement of the study in undergraduate courses, and completed the Project READY questionnaire via the Internet. Participants were recruited from universities across the United States, with an overall response rate of approximately 60\%. The majority of emerging adults were European American (61\% European American, 25\% Asian American, 5\% Latino American, 5\% mixed-biracial, and 4\% African American). Nearly 90\% of emerging adults reported living outside of their parents’ home in an apartment, house, or dormitory. Roughly 20\% of emerging adults had parents with a combined income of less than US$50,000 per year, and about 30\% with a combined income of over US$100,000.

Participants were recruited through faculty’s announcement of the study in undergraduate courses, and completed the Project READY questionnaire via the Internet. Interested students then accessed the study website with a class-specific recruitment code. Informed consent was obtained online, and only after consent was given could the participants begin the questionnaires. Most participants were given a US$20 Amazon gift code for their participation.

Method

Participants and procedures

Participants were drawn from a study of emerging adult college students and their parents entitled Project READY (Researching Emerging Adults’ Developmental Years). This project is a collaborative, multi-site study that was conducted by a consortium of developmental and family scholars, and data used in the current study were collected during 2009–2010. The sample for the current study (age M = 19.87, SD = 2.00, range = 18–29) consisted of 551 undergraduate students (60\% female). Participants were recruited from four universities across the United States, with an overall response rate of approximately 60\%. The majority of emerging adults were European American (61\% European American, 25\% Asian American, 5\% Latino American, 5\% mixed-biracial, and 4\% African American). Nearly 90\% of emerging adults reported living outside of their parents’ home in an apartment, house, or dormitory. Roughly 20\% of emerging adults had parents with a combined income of less than US$50,000 per year, and about 30\% with a combined income of over US$100,000.

Participants were recruited through faculty’s announcement of the study in undergraduate courses, and completed the Project READY questionnaire via the Internet. Interested students then accessed the study website with a class-specific recruitment code. Informed consent was obtained online, and only after consent was given could the participants begin the questionnaires. Most participants were given a US$20 Amazon gift code for their participation.

Measures

Three ethics. Participants completed the 18-item Ethical Values Assessment long form (EVA_L), with six items pertaining to each of the three ethics (Autonomy, Community, Divinity). Participants were asked to respond to “What moral values do you think are important to how you should live at this time in your life?” on a 5-point scale ranging from 1 (not at all important) to 5 (completely important). Table 2 lists all items.

Self-worth. Self-worth was assessed using the self-worth subscale (5-items) from the Self Perceptions Profile for College Students (Neeman & Harter, 1986). Emerging adults responded on a 4-point scale ranging from 1 (not at all true for me) to 4 (very true for me). Sample questions include, “I am often disappointed with myself (reverse scored),” and “I am happy being the way I am.” Higher mean scores represented higher feelings of self-worth (α = .84).

Relationship quality. In order to assess closeness with best friend and parents (mother and father), the intimate disclosure (3 items), affection (3 items), emotional support (3 items) and guidance/advice (3 items) subscales were used from the Social Provisions Questionnaire (Carbery & Buhrmester, 1998). Participants answered questions on a 5-point scale ranging from 1 (little or none) to 5 (the most). Sample questions include, “How often do you turn to this person for support with personal problems?” and “How happy are you with the way things are between you and this person?” Subscales were averaged to create a mean score for relationship quality with friend (α = .96), mother (α = .93), and father (α = .95). Because scales were correlated (r = .22–.51, p < .001) and to increase parsimony, an overall relationship quality scale was calculated by averaging the three scales.

Religious faith. Four items from the Santa Clara Strength of Religious Faith Questionnaire (Lewis, Shevlin, McGuckin, & Navrtil, 2001) were available in the current data set and were used to assess participants’ religious faith (α = .98). Questions were asked on a 4-point scale ranging from 1 (strongly disagree) to 4 (strongly agree). Sample questions include, “I look to my faith as providing meaning and purpose in my life,” and “My relationship with God is extremely important to me.” Higher mean scores indicated higher religious faith.

Results

Confirmatory factor analysis

Data were explored for univariate and multivariate outliers and normality; there were no outliers and all variables were normally distributed. A confirmatory factor analysis (CFA) was conducted using AMOS software (Arbuckle, 2010). It should be noted that missing data (which were very minimal, < 3\%) were handled using the Full Information Maximum Likelihood feature of AMOS. Three latent variables were created with the corresponding six items loading on subscales of Autonomy, Community, and Divinity (18-items total). Model fit was considered acceptable with CFI > .90, TLI > .90, and RMSEA < .08 (Little, 2013).

Based on hypotheses and theory, we examined a three-factor model, and this solution was an acceptable fit to the data, (χ^2(130) = 540.58, p < .001, CFI = .93, TLI = .91, RMSEA = .076), with all variables loading on their respective latent variables (see Table 2 for item correlations and Figure 1 for CFA model). Modification indices were examined and there was no evidence of cross-loading, though correlations between two sets of residuals were recommended for the divinity subscale. Tests of discriminant validity were conducted on the 18-item measure by constraining estimated correlation parameters between constructs to 1.0 and assessing Δχ^2 (Anderson & Gerbing, 1988). Constraining all three correlations (one at a time) to 1.0 each resulted in a decrease in model fit, suggesting that the three variables were distinct constructs. This was true for the correlation between autonomy and community, Δχ^2 = 46.11, p < .001, the correlation between community and divinity, Δχ^2 = 466.37, p < .001, and the correlation between autonomy and divinity, Δχ^2 = 653.63, p < .001. Cronbach’s alphas were calculated, resulting in additional evidence of adequate internal reliability for subscales of Autonomy (6-items, α = .79), Community (6-items, α = .75), and Divinity (6-items,

Note: N = 551. All correlations are significant at p < .05 except for bolded. Items are on a 5-point scale with higher scores indicating greater self-reported importance of the value.
In the regression analysis for religious faith, ethnicity accounted for a significant portion of variance ($\beta = .12, p < .05$), $F(2, 547) = 4.35, p < .05$. At Step 2, variables accounted for a significant portion of variance, $\Delta R^2 = .73, p < .001$; $F(5, 544) = 312.11, p < .001$, $R^2 = .74$, with and Ethic of Divinity significantly associated with religious faith ($\beta = .92, p < .001$). The Ethic of Community was also significantly negatively associated with religious faith ($\beta = -.15, p < .001$), but a positive zero-ordered correlation revealed this to be a suppressor effect due to the correlation between the Ethic of Divinity and Community ($r = .30, p < .001$). Ethic of Autonomy was not significantly associated with religious faith ($\beta = -.02, p = .49$).

**Study 1 discussion**

Consistent with study goals, Study 1 established internal reliability for the EVA_L and supported a three-factor model with 6-item subscales for Autonomy, Community, and Divinity. Further, Study 1...
sought to establish discriminant validity by examining the three ethics as predictors of self-worth, relationship quality, and religious faith, and findings were in line with expectations. More specifically, the Ethic of Autonomy was positively associated with self-worth, as expected. Further, the Ethic of Community was positively associated with relationship quality, supporting the notion that individuals whose moral values revolve primarily around collectivist ideals of interdependence also have strong relationship ties. Finally, the Ethic of Divinity was positively associated with religious faith. Indeed, it should be noted that a relatively small portion of variance was accounted for in the analyses for self-worth and relationship quality, while a relatively large portion of variance was accounted for in the analysis for religious faith, suggesting that an Ethic of Divinity is central to one’s religiousness, while the other two ethics are not as central to these particular outcomes. Further research is needed in this regard to more clearly determine correlates and predictors of the three ethics, but analyses established initial evidence of both convergent and discriminate validity.

Limitations of Study 1 include a relatively homogenous sample and a cross-sectional data set that preclude examination of direction of effects. Also, while Study 1 was conducted on a relatively large sample, it was limited to college students age 18–29 years. Thus, Study 2 sought to build on these findings by validating the EVA_S on a nationally representative sample of adults.

Study 2

The cultural-developmental approach to morality suggests that the multifaceted nature of moral development is most accurately understood by examining both the developmental life period of the individual and the cultural context in which morality is socialized (Jensen, 2008, 2011). There is a sizable body of literature on cultural variations in moral reasoning, as well as an established line of research examining developmental change in morality from childhood through adolescence (e.g., see Jensen, 2015). However, there are a dearth of studies that examine morality with a developmental lens after adolescence, with most studies using emerging adults as a convenience sample (Padilla-Walker, in press) and even fewer studies following changes in moral reasoning over the course of adulthood. While research does suggest that moral reasoning may change and solidify through the course of adulthood (Shweder et al., 1997), there are few developmental theories that claim significant cognitive change past the formative years. However, with continued research suggesting prolonged brain development into emerging and early adulthood and beyond (Gutchess & Boduroglu, 2015; Jetha & Segalowitz, 2012), as well as the influence of social contexts that are associated with morality and that increase in salience during early and middle adulthood (e.g., marriage, parenting, religious attendance), it is important to examine moral reasoning at different ages. Thus, the purpose of Study 2 was to validate the EVA_S, which is a 12-item measure assessing the three-ethics approach to morality, and to examine differences as a function of age in a nationally representative sample of US adults.

Method

Participants and procedures

Participants for this study were taken from the Moral Worldviews Study, which is a survey regarding individuals’ experiences and attitudes toward various aspects of morality. The targeted population was adults 18 years and older, and data used in the current study were collected during March of 2012. The sample for the current study consisted of 1,519 individuals aged 18–93 years (51% female). The majority of participants (72%) were European American (12% Hispanic, 10% African American). Roughly 32% of the sample reported having a Bachelor’s degree or higher, with 40% reporting a high school degree or less. Mean household income was between US$50,000 and US$60,000 per year, with about 30% of the sample reporting making less than US$40,000 per year.

This study used Knowledge Networks (KN) to gather an opinion poll, sampling households from its KnowledgePanel, which is a probability-based web panel designed to be representative of the United States. Panel members were randomly recruited through random digit dialing or probability address-based sampling, and households were provided with access to the Internet if needed. Once household members were recruited for the panel, they were assigned to the Moral Worldviews Study and notified by e-mail with directions for survey-taking. Surveys took approximately 40 minutes to complete and participants were offered US$5 (or equivalent incentive, e.g., raffle) for completion. The response rate was 61%.

Measures

Participants completed the 12-item Ethical Values Assessment-Short Form (EVA_S). Items were selected from the longer measure based on factor loading and the conceptual considerations discussed above for EVA_L. Participants were asked to respond to “What moral values do you think are important to how you should live at this time in your life?” on a 5-point scale ranging from 1 (not at all important) to 5 (completely important). All items are contained in Table 3.

Results

Data were explored for univariate and multivariate outliers and normality; there were no outliers and all variables were normally distributed. A confirmatory factor analysis (CFA) was conducted using AMOS software (Arbuckle, 2010). It should be noted that missing data (which were very minimal, <1%) were handled using the Full Information Maximum Likelihood feature of AMOS. Three latent variables were created with the corresponding 4-items loading on subscales of Autonomy, Community, and Divinity (12-items total). Model fit was considered acceptable with CFI > .90, TLI > .90, and RMSEA < .08 (Little, 2013).

Based on hypotheses, we examined a three-factor model, and this solution fit the data well, \( \chi^2(50) = 373.73, \text{ } p < .001, \text{ CFI = .97, TLI = .96, RMSEA = .065.} \) All variables loaded on their respective latent variables (see Table 3 for item correlations and Figure 2 for CFA model). Modification indices were examined, and there was one covariance that suggested a cross-loading item, item number 5 (I should take care of my family), and one recommended correlation between residuals for the community subscale. The model was re-run with the cross-loaded item deleted from the community variable, \( \chi^2(40) = 192.69, \text{ } p < .001, \text{ CFI = .98, TLI = .98, RMSEA = .05.} \) and there were no additional modification indices that had a significant impact on model fit. With this item deleted, the covariance between the autonomy and community variables decreased to .79. Tests of discriminant validity were conducted on the 11-item measure by constraining estimated
correlation parameters between constructs to 1.0 and assessing $\chi^2$ (Anderson & Gerbing, 1988). Constraining all three correlations (one at a time) resulted in a decrease in model fit, suggesting that the three variables were distinct constructs. This was true for the correlation between autonomy and community ($\chi^2 = 109.01, p < .001$), the correlation between community and divinity ($\chi^2 = 304.69, p < .001$), and the correlation between autonomy and divinity ($\chi^2 = 1695.37, p < .001$). Cronbach's alphas were calculated, resulting in additional evidence of adequate internal reliability for subscales of Autonomy ($a = .82$), Community ($a = .74$; 3-items, $a = .72$), and Divinity (4-items, $a = .94$). It should be noted that we reported on the full 12-item measure in the figure because this item did not seem to act similarly in Study 1 and may only be problematic in this sample.

Multiple group analyses
While this study confirms the overall reliability of the short-form of the EVA, this data set also allowed us to examine the measure among different age groups. Thus, a multiple group analysis was conducted on the three-factor solution, with four age groups: 18–29 years (emerging adulthood), 30–44 years (early adulthood), 45–59 years (middle adulthood), and 60+ years (late adulthood). These age group designations and their corresponding ages are common in the developmental psychology literature. While there is notable cultural variation on ways of dividing the adult life course, the present divisions overlap with those used in standard lifespan textbooks (e.g., Arnett, 2012; Papalia & Feldman, 2012; Santrock, 2012) and are applicable to the present sample. Multiple group analyses were conducted to determine whether invariance could be established across age groups on both factor loadings (weak invariance) and intercepts (strong invariance), which is what is needed to compare means across groups. In order to establish invariance of factor loadings, multiple group analyses compared a fully unconstrained model to a model where factor loadings were constrained. Then, this weak invariance model was compared to a model where intercepts were also constrained to be equal. The measure was considered to be invariant across age if the decrease in CFI at each step was not greater than .01 (Little, 2013). As can be seen in Table 4, invariance was established for factor loadings, but not for intercepts (so weak invariance was achieved, but not strong).

Multiple group analyses for each subscale. To understand more fully how this measure differed by age, we first conducted a multiple group analysis on all three subscales separately to determine if one ethic primarily accounted for the differences. Using the same criteria described above, it was determined that strong invariance was not achieved for either autonomy or community, but it was for divinity (see Table 4). This suggests that the mean values of divinity can be meaningfully compared across age groups. As a next step in understanding the autonomy and community subscales, we examined individual items on these two subscales to see if one item was primarily responsible for the lack of invariance, but no single item stood out in this analyses by contributing
uniquely to the .01 drop in CFI. We then compared all four age
groups to one another (constraining both factor loadings and then
intercepts group by group) to see which age groups were contributing
to the measurement variance. For example, we first constrained fac-
tor loadings (and then intercepts) for emerging adulthood and early
adulthood to be equal, followed by emerging adulthood and middle
adulthood (and so on), until all 12 possible comparisons were con-
ducted (6 for factor loadings, 6 for intercepts). Again, we used the
criteria of a drop in CFI < .01 as an indication of invariance.

This analysis for the Autonomy subscale suggested the only
constraint to result in a reduction in CFI > .01 was when constrain-
ing intercepts from emerging adulthood to late adulthood to be
equal (ΔCFI = .014). For the Community subscale constraining fac-
tor loadings between emerging adulthood and middle adulthood
(ΔCFI = .022) and between early adulthood and middle adulthood
(ΔCFI = .014); and constraining intercepts between emerging
adulthood and middle adulthood (ΔCFI = .017) resulted in a reduc-
tion in CFI > .01. Table 5 represents a repeated measures ANOVA
on the three subscales for the four different age groups, though
clearly not all of these mean differences are meaningful because
invariance was not achieved across all ages. With that in mind,
results suggest that on all three ethics, mean values are similar for
emerging and early adulthood, and are significantly higher for

Figure 2. Initial SEM for EVA_Short-Form.

Note. N = 1519. Squared multiple correlations are in italics. 95% confidence intervals are in brackets. All values are standardized.
middle and late adulthood. We also computed Cronbach’s alphas for each subscale separately by age (emerging, early, middle, and late adulthood, respectively), Autonomy (α = .90, .89, .69, .75), Community (α = .76, .82, .68, .69), and Divinity (α = .95, .95, .94, .94). Again, no specific item stood out as problematic to reliability, but patterns suggested Autonomy and Community scales were slightly less reliable in older age groups.

Taken together, the above analyses suggest that the divinity short form of the EVA is comparable across all age groups, while caution should be taken when comparing the Autonomy and Community scales across age groups. The Autonomy scale seems to be comparable across most groups, except emerging adults and late adults, while the Community scale varied the most as a function of age and had the least consistent internal reliability, so mean comparisons may be invalid.

### Study 2 discussion

Results from Study 2 suggested that the EVA_S functions at least as well as the EVA_L, providing support for using either form to assess the three ethics in a variety of age groups. That being said, future studies should use caution with the one item from the Community scale that showed evidence of cross-loading. Although this item was not a problem with the EVA_L, it did present problems with the EVA_S and contributed to a higher covariance between autonomy and community subscales. Future research should explore whether this is unique to the current sample, or a prevailing issue in need of further explanation. Study 2 also contributed by allowing for analyses by age, and suggested that how moral reasoning is conceptualized, especially as it relates to an Ethic of Community, may change as a function of development through adulthood. While this does not allow for comparison across all age groups on all ethics, it is an interesting finding suggesting a need for a more in-depth look at the ways in which the three ethics change over the course of adulthood and how this change is associated with behavior. Means in the current study suggest that all three ethics may become more salient over time, perhaps as a function of decreases in exploration and a greater solidifying of moral values into adulthood (Padilla-Walker & Nelson, 2015). However, this could also be a cohort effect in that the older generations in the current study may endorse moral values more because they mean something different to that generation than they do to the younger generation (Hart & Sulik, 2014). Thus, while this study benefitted from the strength of a nationally representative sample, researchers will need to utilize long-term longitudinal studies to more clearly determine how the three ethics develop over time and how they are cognitively and behaviorally negotiated.

### General discussion

The present research provided support for the internal reliability and validity of the long and short forms of the Ethical Values Assessment (EVA). As described at the outset, the purpose of EVA is to assess a broad and diverse set of moral values, thus, EVA was based on theory and research on the three Ethics of Autonomy, Community, and Divinity. Given the present validation, we would suggest that EVA may now be deployed to extend both theory and research in moral psychology. This includes large-scale examinations of the intersection of culture and development in use of the three ethics, and the relations of the ethics to other cognitive, emotional, and behavioral variables. Trommsdorff (2015b), for example, has put forth a series of specific questions as to how the three ethics relate to prosocial behaviors, including in regards to those who are familiar versus strangers, and how both age and culture may be of significance.

The present validation study was limited to participants from the United States. As described above, the development of EVA was based on research with the standard coding manual for the three ethics which has been used across highly diverse cultures. Nonetheless, additional validation of the measure from other nations would be a next step. It would also be fruitful to extend the present study to older children and adolescents. Further, it is of note that autonomy and community subscales were strongly correlated in latent models, though tests of discriminate validity suggested meaningful differences. Future research should continue to determine the ways in which the three ethics overlap, and in which ways they are unique.

As the present findings indicate, EVA has applicability across the adult life course, although interpretations of findings for different age groups will need to be made with care. We know that as people develop from childhood through adulthood they become increasingly culturally diverse in their moralities. In today’s globalizing world, the socialization and expertise that is gained with age often involves familiarity with the moral values of more than one culture. EVA_L and EVA_S hold the prospect of being useful in validly assessing diverse and intersecting moral values across most of the life course.

### Funding

Data collection for the Measuring Morality project (Study 2) was supported by a grant from the John Templeton Foundation (grant number 21869).

### Note

1. A separate CFA analysis was also run accounting for the sampling weights used in Study 2. There was very minimal change in factor loadings and covariances (< .001).
